

Docstring Style:

- Start with triple quotation marks followed by a one line description of the function's purpose. The description should start with a verb.
- Add a 'Parameters:' section listing each parameter with its expected data type.
- Add a 'Returns:' section that lists the expected return type(s) and meaning(s).
- End with triple quotation marks.

Example:

```
def addup(param1,param2):  
    """Adds two values  
    Parameters:  
        param1, number  
        param2, number  
    Returns:  
        a number, the sum of the parameters  
    """  
    return param1 + param2
```

Note: In our example above, the function can accept any numeric data type, so the type is number. However, if the parameter was required to be one data type, like int, the parameter type should specify int.
